24 **Abstract**

25 Crop rotation and biofertilizer application have historically been employed as efficient
26 management strategies for soil-borne disease suppression through soil microbiome
27 manipulation. However, how this occurs and to what extent the combination of
28 methods affects the microbiota reconstruction of diseased soil is unknown. In this
29 study, pineapple-banana rotation combined with biofertilizer application was used to
30 suppress banana Fusarium wilt disease, and the effects on both bacterial and fungal
31 communities were investigated using the MiSeq Illumina sequencing platform. Our
32 results showed that pineapple-banana rotation significantly reduced Fusarium wilt
33 disease incidence and the application of biofertilizer caused additional suppression.
34 Bacterial and fungal communities thrived using rotation combined with biofertilizer
35 application: taxonomic and phylogenetic α -diversity of both bacteria and fungi
36 increased along with disease suppression. Between the two strategies, biofertilizer
37 application predominantly affected both bacterial and fungal community composition
38 compared to rotation. *Burkholderia* genus may have been attributed to the general wilt
39 suppression for its change in network structure and high relative importance in linear
40 models. Our results indicated that pineapple-banana rotation combined with
41 biofertilizer application has strong potential for the sustainable management of banana
42 Fusarium wilt disease.

48

49 **1 Introduction**

50 Banana Fusarium wilt disease caused by *Fusarium oxysporum* f. sp. *cubense* (FOC)
51 race 4 forms a major constraint on the yield and quality of banana production (Ploetz,
52 2015; Butler, 2013). Multiple studies have revealed that individual measures, such as
53 fumigation (Duniway, 2003; Liu et al., 2016), chemical fungicides (Nel et al., 2007),
54 crop rotation (Zhang et al., 2013b), and bio-control (Wang et al., 2013) have
55 particular effects on reducing the incidence of soil-borne diseases by disrupting soil
56 microbial community membership and structure. Traditionally, fumigation, chemical
57 fungicides, or crop rotation is used in fields with high incidence rates, and bio-control
58 is used in low- or new-incidence fields because of its apparent mild effect (Shen et al.,
59 2018). However, single measures often have limited effectiveness, and a few studies
60 regarding soil-borne disease suppression focused on using multiple strategies to
61 improve control efficiency. Like Shen et al. (2018) reported that biofertilizer
62 application after fumigation with lime and ammonium bicarbonate was an effective
63 strategy to control banana Fusarium wilt disease. Thus, while many measures can
64 individually slow down the spread of Fusarium wilt disease (Pda et al., 2017), control
65 effects can be accelerated and amplified by using more than one agricultural practice.

66 Among the management strategies, chemical pesticides are optimally effective
67 against soil-borne plant pathogens, but this strategy is environmentally hazardous, and
68 not only causes soil and water pollution but also induces the emergence of drug-
69 resistant strains (Le et al., 2016). Biological control using beneficial soil
70 microorganisms such as *Bacillus* and *Trichoderma* against soil-borne pathogens is
71 considered as a sustainable alternative to chemical pesticides (Alabouvette et al., 2009;
72 Fravel et al., 2003; Qiu et al., 2012). Biofertilizers combine the advantages of
73 introducing beneficial microbes with organic material that not only occupy niches but
74 also create additional niches for beneficial indigenous microbes (Cai et al., 2017;

75 Zhang et al., 2013). In our previous study, we developed a biofertilizer containing the
76 *Bacillus* strain isolated from the rhizosphere of a continuously cropped banana that
77 promoted plant growth and suppressed the banana Fusarium wilt (Shen et al., 2015;
78 Fu et al., 2016; Fu et al., 2017). Therefore, biofertilizer application is a practicable
79 and worthy measure for banana Fusarium wilt suppression.

80 In addition, crop rotation is also considered a highly efficient and
81 environmentally friendly alternative method in soil-borne disease control (Krupinsky
82 et al., 2002). Crop rotation breaks the microflora and chemical characteristics of
83 continuously mono-cropped soil leading to the control of soil-borne diseases (Christen
84 and Sieling, 2010; Yin et al., 2010). The mechanisms of soil-borne disease
85 suppression induced by crop rotation include inhibition of pathogen reproduction
86 through allelochemical secretion, stimulation of antagonistic microbes against
87 pathogens, and improvement of rhizosphere microbial community structure by
88 introducing different carbon compounds into the soil through root exudates or
89 residues (Robert et al., 2014). In our previous study, besides biofertilizer application,
90 our work also showed that the banana-pineapple rotation efficiently suppressed the
91 banana Fusarium wilt disease (Wang et al., 2015). However, the combined control
92 efficiency of the two measures (pineapple-banana rotation plus biofertilizer
93 application) remains unknown. Thus, there is a great need to explore efficient disease
94 suppressing-combined approaches for the banana Fusarium wilt control and to
95 progress towards maintaining sustainable worldwide industrial banana development.

96 The occurrence of soil-borne disease is mainly due to the imbalance of soil
97 microbial communities caused by soil-borne pathogen blooms (Mendes et al., 2014).
98 Effective soil-borne disease suppression management strategies must demonstrate
99 significant changes in the soil microbial community in addition to pathogen
100 minimization (Cha et al., 2016; Chaparro et al., 2012; Gerbore et al., 2014; Mazzola

101 and Freilich, 2017). Our previous reports proved the effectiveness of microbial agents
102 for biocontrol by changing the structure of soil microbial communities (Fu et al., 2017;
103 Shen et al., 2015). We also investigated the influences of quarterly rotation (pineapple)
104 on *Fusarium* population density and soil microbial community structure while
105 attempting to explore the mechanisms of pineapple-banana rotation on soil borne-
106 disease suppression (Wang et al., 2015). Our results suggested that fungal community
107 structure and several genera introduced in the rotation season may have been the most
108 critical factors in decreasing soil *Fusarium* population.

109 Unlike intercropping, controlling *Fusarium* pathogen accumulation through
110 effective crop rotation should be maintained for at least two seasons, including
111 rotation and a subsequent season (Bullock, 1992; Lupwayi et al., 1998). The
112 pineapple and banana growth cycles in our rotation pattern require long durations
113 (almost 15 and 10 months, respectively, in Hainan Province, China). Thus, the soil
114 microbial community structure of the original season is very important in evaluating
115 rotation validity. Furthermore, how the soil microbial community structure changes
116 using the combined control efficiencies of the two measures (pineapple-banana
117 rotation and biofertilizer application) remains unknown.

118 We hypothesized that *Fusarium* wilt can be effectively controlled in high-
119 disease incidence fields by pineapple-banana rotation and that the control efficiency
120 can be improved by adding biocontrol to the rotation. In addition, this scheme will
121 concurrently change the soil microbial community membership and structure.
122 Therefore, based on our previous research, we conducted field experiments to
123 investigate the effects of pineapple-banana rotation combined with biofertilizer on
124 next season banana *Fusarium* wilt disease suppression and soil microbial communities.
125 Our objectives were to 1) determine the direct effects of pineapple-banana rotation
126 alone and pineapple-banana rotation combined with biofertilizer application to control

127 banana Fusarium wilt disease; 2) explore the characteristics of the soil microbial
128 communities prompted by crop rotation and biocontrol strategies after banana harvest
129 using the MiSeq platform, and 3) evaluate the probable disease suppression
130 mechanisms caused by rotation and biocontrol strategy.

131 **2 Materials and Methods**

132 **2.1 Field experimental design**

133 The field experiment was set up at the site of Hainan Wanzhong Industrial Co., Ltd.,
134 China, a company that specialized in banana planting during December 2011 to June
135 2014. The field soil had a chemical background of pH 5.12, soil organic matter (SOM)
136 5.57 g kg^{-1} , $\text{NH}_4^+\text{-N } 7.39 \text{ mg kg}^{-1}$, $\text{NO}_3^-\text{-N } 6.68 \text{ mg kg}^{-1}$, available P 56.9 mg kg^{-1} and
137 available K 176.4 mg kg^{-1} . The organic fertilizer (OF) used in our study was supplied
138 by Lianye Biofertilizer Engineering Center, Ltd., Jiangsu, China, which was the first
139 fermentation of amino acid fertilizer and pig manure with a 2:3 weight ratio,
140 respectively. The biofertilizer (BIO) was a secondary fermentation based on OF
141 according to the solid fermentation method (Wang et al., 2013). The research was
142 carried out in a field in which a serious Fusarium wilt disease incidence ($> 50\%$) was
143 observed after continuous banana cropping for 6 years. Nine replicates were set up in
144 each treatment with a randomized complete block design, and the area of each block
145 was 300 m^2 . Banana cultivar *Musa acuminata AAA Cavendish cv. Brazil* and the
146 pineapple cultivar Golden pineapple were used in the field experiment. Three
147 treatments were assigned: (1) banana continuously cropped for two years with
148 common organic fertilizer application (BOF); (2) banana planted after an eighteen-
149 month pineapple rotation with common organic fertilizer application in the banana
150 season (POF); and (3) banana planted after an eighteen-month pineapple rotation
151 treatment with biofertilizer application (PBIO). In the rotation system, pineapple and

152 banana were planted at the densities of 45000 and 2,400 seedlings ha⁻¹, respectively.
153 All organic fertilizer was applied to the soil at once as base fertilizer before banana
154 planting. Other measures were consistent with common banana production.

155 **2.2 Banana Fusarium wilt disease incidence statistics**

156 Old leaves yellowing, stem crack and new leaves diminishing were the three typical
157 wilt symptoms of banana Fusarium wilt disease. Disease incidence was calculated
158 based on the appearance of all three symptoms weekly since the first sick banana
159 plant appeared. Finally, banana wilt disease incidence was determined at the harvest
160 time. The percentage of sick plants among the total banana plants was calculated as
161 the Fusarium wilt disease incidence.

162 **2.3 Soil sample collection and DNA extraction**

163 During the harvest time of last banana planting season, five healthy plants were
164 randomly picked in each biological replicate plot for soil sampling. Soil samples were
165 collected from four random sites around the banana plant at 10 cm distance, and a soil
166 column was picked out at the depth of 20 cm using a soil borer at each sampling site.
167 All five soil columns from each biological replicate plot were mixed for DNA
168 extraction. All mixed samples were placed in cold storage and transported to the
169 laboratory. After passing soil through a 2-mm sieve, total soil DNA was extracted
170 using Clean Soil DNA Isolation Kits (MoBio Laboratories Inc., Carlsbad, USA) from
171 fine-grained soil. After the determination of DNA concentration and quality using
172 NanoDrop 2000 (Thermo Scientific, USA), soil DNA was diluted to a concentration
173 of 20 ng µl⁻¹ for PCR amplification.

174 **2.4 Polymerase chain reaction amplification and Illumina Miseq sequencing**

175 Primers F520 (5'-AYTGGGYDTAAAGNG-3') and R802 (5'-
176 TACNVGGGTATCTAATCC-3') were chosen to amplify the V4 regions of 16 S

177 rRNA gene (Claesson et al., 2009). Primers ITS (5'-GGA AGT AAA AGT CGT
178 AAC AAG G-3') and ITS (5'-TCC TCC GCT TAT TGA TAT GC-3') were chosen
179 for amplification of the fungal ITS region (Schoch et al., 2012).

180 PCR reactions for each sample were performed according to the established
181 protocols of Xiong et al. (2016). A total of 27 cycles were performed to amplify the
182 templates. After purification, PCR products were diluted to a concentration of 10 ng
183 μl^{-1} . Fungal and bacterial PCR products sequencing were performed on the Illumina
184 MiSeq platform of Personal Biological Co., Ltd (Shanghai, China).

185 **2.5 Bioinformatic analysis**

186 Raw sequences were separated based on the unique 6-bp barcode and sheared of the
187 adaptor and primer using QIIME (Caporaso et al., 2010). Forward and reverse
188 sequences were merged after the removal of low-quality sequences. Then, the merged
189 sequences were processed to build the operational taxonomic unit (OTU) at an
190 identity level of 97% according to the UPARSE pipeline. Next, representative
191 sequences of each OTU were classified in the RDP and UNITE databases for bacteria
192 and fungi, respectively (Edgar, 2013; Wang et al., 2007). All raw sequences were
193 deposited in NCBI under the accession number SRP234066.

194 To compare the relative levels of OTU diversity across all samples, a rarefaction
195 curve was formed using Mothur software (Schloss et al., 2009). The fungal and
196 bacterial diversity was estimated using phylogenetic diversity (PD) indices and Chao1
197 richness, which were also calculated based on neighbor-joining phylogenetic trees
198 generated using Mothur pipeline (Faith, 1992).

199 To compare bacterial and fungal community structures among all soil samples,
200 principal coordinate analysis (PCoA) was set up based on the unweighted UniFrac
201 metric matrix (Lozupone et al., 2005). Multiple regression tree (MRT), based on

202 Bray-Curtis distance metric, was carried out to evaluate the effects of rotation and
203 fertilizer type on the whole soil bacterial and fungal community by using vegan and
204 MVPART wrap package in R (version 3.2.0). In addition, to exclude the influence of
205 low abundance species, only the OTUs with the average relative abundance of equal
206 or greater than 0.1% in each sample were retained (defined as retained OTUs).

207 **2.6 Network analyses**

208 Based on retained OTUs, interaction networks between OTUs were constructed using
209 the phylogenetic Molecular Ecological Network (pMEN) method according to Zhou
210 et al. (2011) and Deng et al. (2012). All analyses were performed using the Molecular
211 Ecological Network Analyses Pipeline (MENA). Cytoscape 2.8.2 software was used
212 to visualize the network.

213 **2.7 Statistical analysis**

214 Statistical difference analysis among three treatments was carried out using SPSS
215 20.0 and R software. Pearson correlations among disease incidence, different Phylum
216 and *Fusarium*-relative abundance were analyzed in R. Linear models analysis was
217 performed using R after stepwise model selection considering Akaike information
218 criteria.

219 **3 Results**

220 **3.1 Disease incidence and relative abundance of *Fusarium***

221 Pineapple rotation and biofertilizer application effectively reduced the *Fusarium* wilt
222 disease incidence and the relative abundance of *Fusarium* in the next season's banana
223 plantation (**Fig. 1A and B**). The incidence of banana *Fusarium* wilt in the POF and
224 PBIO treatments was 33.3% and 12.3%, respectively, which was significantly lower
225 than that in the BOF treatment (66.8%). PBIO treatment of rotation and biofertilizer

226 application showed the lowest disease incidence with a 63.1% decrease compared to
 227 POF (**Fig. 1B and Table S1**). The relative abundance of *Fusarium* showed the same
 228 tendency with disease incidence, so the relative abundance of *Fusarium* and disease
 229 incidence were significantly correlated as revealed by MiSeq sequencing data (**Fig.**
 230 **1C**).

231

232

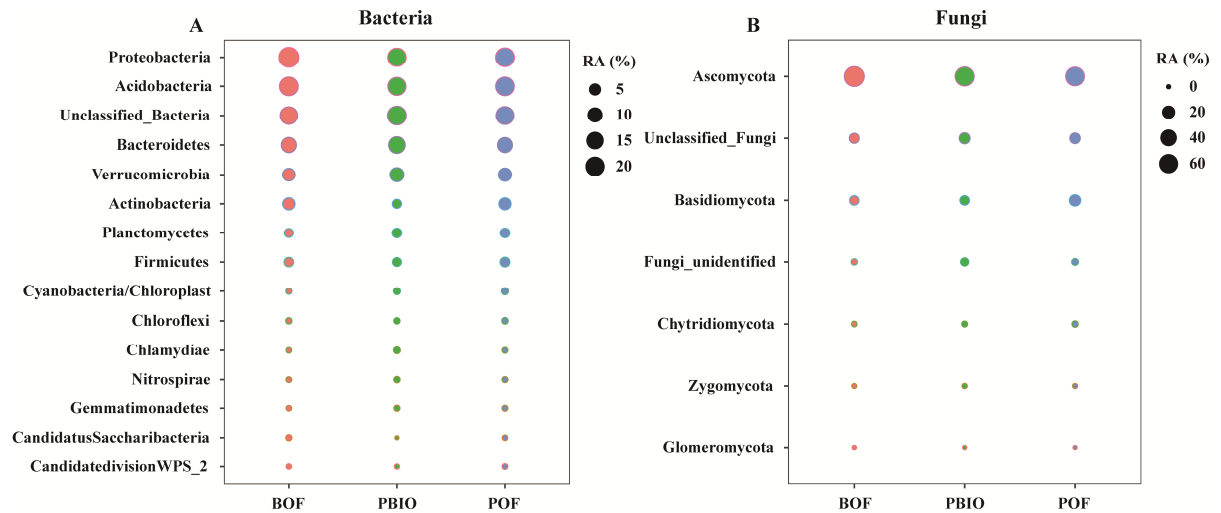

233 **Figure 1. Relative abundance of *Fusarium* (A), *Fusarium* wilt disease incidence (B) and**
 234 **Pearson correlations between *Fusarium* wilt disease incidence and *Fusarium* relative**
 235 **abundance (C).** BOF = banana continuously cropped with OF application; POF = banana-
 236 pineapple rotation with OF application in the banana season; and PBIO = banana-pineapple
 237 rotation with BIO application in the banana season. Bars above the histogram represent
 238 standard errors and different letters indicate significant differences ($p < 0.05$) according to
 239 multivariate variance analysis and multiple comparison results.

240 3.2 General analyses of the high-throughput sequencing data

241 After quality control, 908,506 *16S rRNA* and 1,950,262 ITS sequences were retained
 242 and based on 97% similarity, a total of 8,346 *16S* and 5,647 ITS operational
 243 taxonomic units (OTUs) were obtained. For bacteria, Acidobacteria, Actinobacteria,
 244 Bacteroidetes, Firmicutes, Proteobacteria and Verrucomicrobia were the most
 245 abundant phyla with >1% relative abundances. For fungi, Ascomycota, followed by
 246 Basidiomycota, Chytridiomycota, Zycomycota, and Glomeromycota were the
 247 abundant phyla (**Fig. 2**). ANOVA showed that Chlamydiae, Cyanbacteria/chloroplast,

248 Gemmatimonadetes, Nitrospirae, Planctomycetes, and Verrucomicrobia abundances
 249 were significantly higher in the PBIO and POF treatment samples than those in the
 250 BOF treatment, and the relative abundance of Ascomycota was lower in the PBIO
 251 treatment (Duncan test, $p < 0.05$).

252

253

254 **Figure 2. Bubble chart of bacterial (A) and fungal (B) phyla in BOF, POF and PBIO**
 255 **treatments.** BOF = banana continuously cropped with OF application; POF = banana-
 256 pineapple rotation with OF application in the banana season; and PBIO = banana-pineapple
 257 rotation with BIO application in the banana season; Values represent the average abundance
 258 across the nine replicate libraries for soil samples collected from each treatment.

259

260 3.3 Effect of pineapple rotation and biofertilizer application on soil microbial 261 diversity and community structure

262 Rarefaction analyses, Chao1 and Faith's PD were performed to characterize α -
 263 diversity. Rarefaction analyses showed that the number of OTUs tended to smooth at
 264 14,900 selected bacterial sequences and 34,943 fungal sequences. Compared to BOF
 265 treatment, more OTUs were observed in POF and PBIO treatments, both for bacteria
 266 and fungi, and the PBIO treatment exhibited the highest value of all treatments (**Table**

267 **1, Fig. S1).** Compared to BOF treatment, the pineapple-banana rotation treatments,
 268 POF and PBIO, increased both taxonomic and phylogenetic α -diversity of both
 269 bacteria and fungi. In addition, PBIO treatment showed the highest Chao1 richness
 270 and Faith's PD values (**Table 1**).

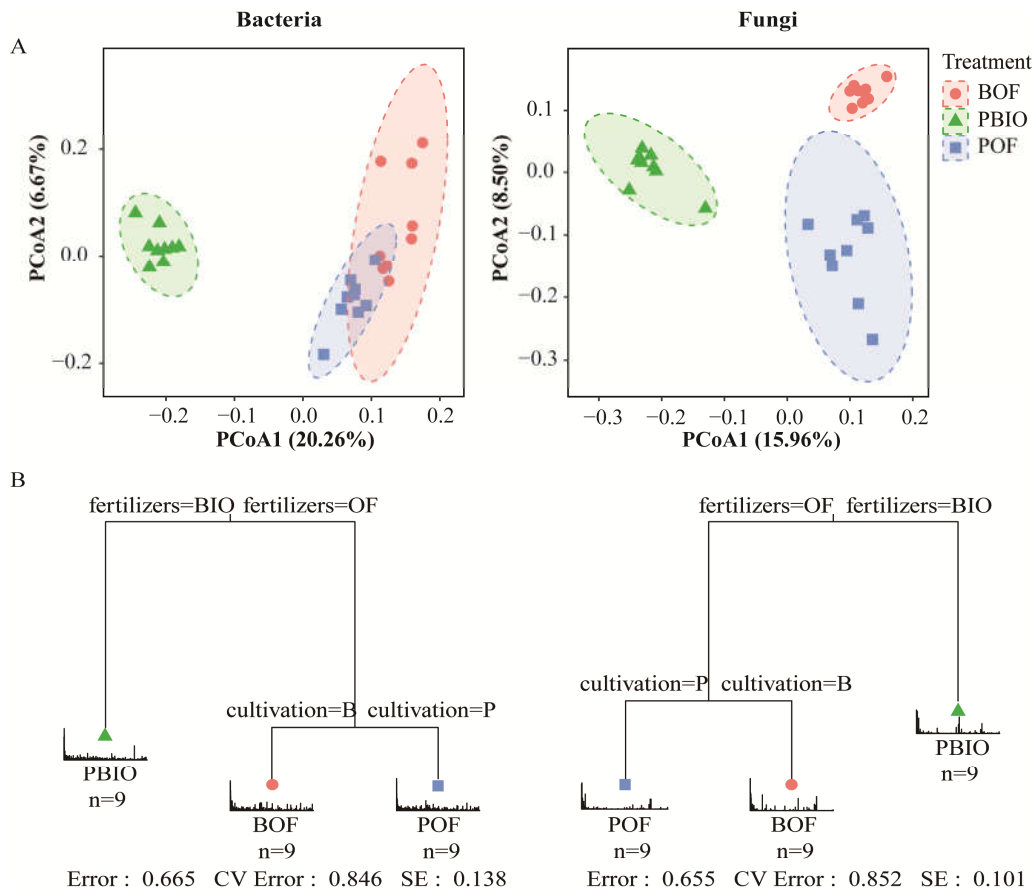

271 **Table 1.** Bacterial and fungal α -diversity indexes of the three treatments. BOF = banana
 272 continuously cropped with OF application; POF = banana-pineapple rotation with OF
 273 application in the banana season; PBIO = banana-pineapple rotation with BIO application in
 274 the banana season; Values represent the average index of nine replicates. Means followed by
 275 different letters for a given factor are significantly different ($p < 0.05$; Duncan test).

	Treatment	Numbers of Otus	Chao1	Faith's PD
Bacteria	BOF	2606 ± 71b	3906.81 ± 275.21 b	48.47 ± 1.51 b
	POF	2963 ± 613 a	4444.28 ± 189.98 a	51.61 ± 0.87 a
	PBIO	3210 ± 108 a	4751.95 ± 149.49 a	52.10 ± 1.11 a
Fungi	BOF	1163 ± 64 b	1751.71 ± 74.85 a	114.88 ± 4.78 b
	POF	1277 ± 708 ab	1705.78 ± 126.73 a	120.24 ± 2.12 b
	PBIO	1496 ± 980 a	2096.32 ± 323.60 a	127.31 ± 7.91 a

276

277 We evaluated microbial community structure by using PCoA based on a UniFrac
 278 unweighted distance matrix to analyze differences in community composition of three
 279 treatments. Fungal PCoA showed three distinct groups representing samples taken
 280 from three treatments; however, bacterial PCoA showed only two groups.
 281 Unweighted UniFrac distances showed that PBIO treatment was separate from BOF
 282 and POF treatments along the first component (PCoA1) both in bacteria and fungi.
 283 POF treatment was separated from BOF treatment along the second component in
 284 fungi, whereas in bacteria, POF and BOF treatments were not separate along the
 285 second component (**Fig. 3A**).

286 Furthermore, MRT results indicated that biofertilizer application had the largest
 287 deterministic influence on the composition of both bacterial and fungal communities,
 288 and cultivation was secondarily important. Driven by fertilization, PBIO treatment
 289 was separated from BOF and POF treatments, and then BOF and POF treatments
 290 were driven by cultivation (**Fig. 3B**).

291 **Figure 3. (A) UniFrac-unweighted principal coordinate analysis of fungal and bacterial**
 292 **community structures in different treatments. (B) Multiple regression tree (MRT)**
 293 **analysis for the bacterial and fungal communities showed the variables of fertilization**
 294 **and cultivation in each branch.** BOF = banana continuously cropped with OF application;
 295 POF = banana-pineapple rotation with OF application in the banana season; PBIO = banana-
 296 pineapple rotation with BIO application in the banana season.

298 **3.4 Effect of pineapple rotation and biofertilizer application on soil fungal and**
 299 **bacterial community composition**

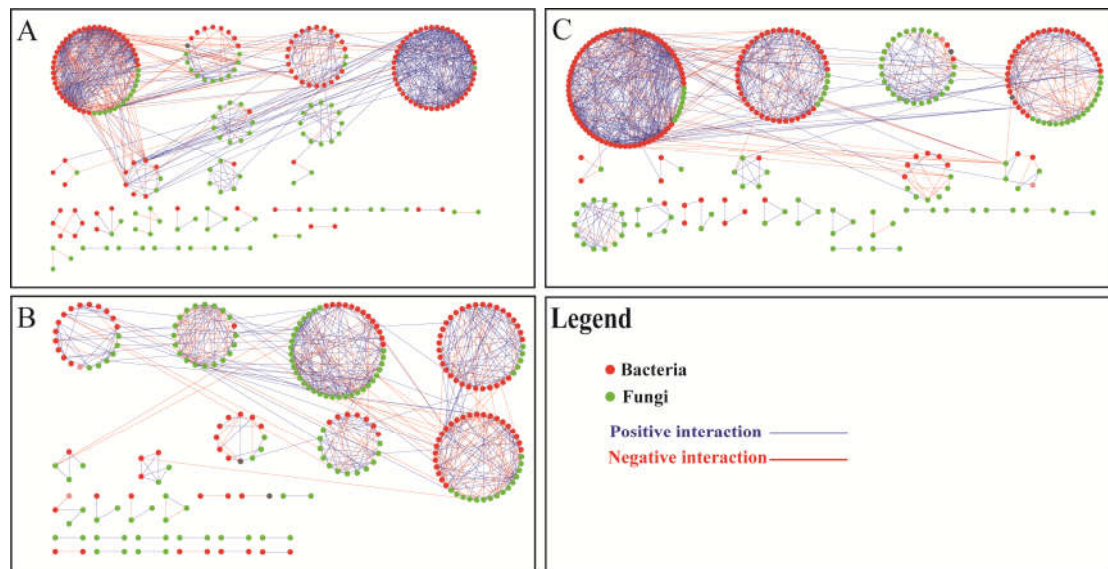

300 The results of the phyla correlation with *Fusarium* abundance showed that seven
 301 bacterial phyla and three fungal phyla were significantly correlated with pathogen
 302 abundance (Tables S3 and S4). Moreover, the correlation of fungi was significantly
 303 higher with *Fusarium* abundance compared to bacteria based on the percentage of
 304 *Fusarium*-related phyla (Fig. 4B).

305
 306 **Figure 4. Relative abundance of key phyla and linear regression relationship between**
 307 **key phyla and disease incidence (A). Percentage of *Fusarium* related bacterial and**
 308 **fungal phyla in all treatments (B). BOF = banana continuously cropped with OF application;**
 309 **POF = banana-pineapple rotation with OF application in the banana season; PBIO = banana-**
 310 **pineapple rotation with BIO application in the banana season. Different letters above the bars**
 311 **indicate a significant difference at the 0.05 probability level according to the Duncan test.**

312 3.5 Key topological properties of the networks

313 We built networks to show interactions among genera in different treatments using
 314 OTUs with a relative abundance greater than 0.1%. A total of 301 OTUs were
 315 selected from the BOF treatment (122 bacterial and 179 fungal), 323 OTUs were
 316 selected from the PBIO treatment (152 bacterial and 171 fungal), and 324 OTUs were
 317 selected from the POF treatment (140 bacterial and 184 fungal). Random matrix
 318 theory was used to build the networks. As shown in **Fig. 5**, each node represents an
 319 OTU, each link shows a significant correlation between two OTUs, red and green
 320 represent bacterial and fungal OTUs, respectively, and blue and red represent positive
 321 and negative correlations, respectively.

322
 323 **Figure 5. Network plots of bacterial and fungal communities in soil BOF (A), PBIO (B)**
 324 **and POF(C).** BOF = banana continuously cropped with OF application; POF = banana-
 325 pineapple rotation with OF application in the banana season; PBIO = banana-pineapple
 326 rotation with BIO application in the banana season; Red nodes indicate bacteria; Green nodes
 327 indicate fungi; red lines between nodes (links) indicate negative interaction; and blue lines
 328 indicate positive interaction.

329

330 Networks with 286 (143 bacterial and 98 fungal), 245 (122 bacterial and 123
 331 fungal), and 241 (163 bacterial and 123 fungal) nodes were selected from the BOF,

332 PBIO, and POF treatments, respectively. The F/B ratios that represent the ratio of
 333 fungal to bacterial nodes were 0.69, 1.01, and 0.75 in the BOF, PBIO, and POF
 334 treatments, respectively. These results suggest more active fungal OTUs in the PBIO
 335 treatment followed by the POF and BOF treatments.

336 The structure index network from different treatments showed 24, 28, and 30
 337 modules in the BOF, PBIO, and POF treatments, respectively (**Table 2**).

338 **Table 2.** Topological properties of the empirical and associated random pMENS of microbial
 339 communities under BOF, POF and PBIO. BOF = banana continuously cropped with OF
 340 application; POF = banana-pineapple rotation with OF application in the banana season;
 341 PBIO = banana-pineapple rotation with BIO application in the banana season; Avg K =
 342 average connectivity; Avg CC = average clustering coefficient; and GD = average path
 343 distance.

Treatment	Network size	R ²	Empirical networks				Random networks		
			AvgK	AvgCC	GD	Modularity	AvgCC	GD	Modularity
BOF	241	0.793	6.71	0.366	2.921	0.62 (30)	0.073	2.96	0.322
POF	286	0.796	5.64	0.412	3.739	0.64 (24)	0.041	3.34	0.385
PBIO	245	0.739	5.16	0.397	3.642	0.72 (28)	0.033	3.28	0.407

344

345 The threshold value Z_i measures the connected degree between two nodes in the
 346 same module, and P_i measures the connected degree between two nodes from
 347 different modules. According to the Z_i and P_i values found in our study, all nodes
 348 were divided into four categories (**Fig. 6**). Three nodes, two from the PBIO network
 349 and one from the POF network, were categorized as generalists (module hubs) with
 350 intense connectivity to many nodes in the same modules. However, there was no
 351 module hub found in the BOF network. Fourteen nodes were categorized as
 352 connectors (generalists) with high connectivity to several modules, eight from the

353 BOF network and six from the PBIO network. Interestingly, module hubs (generalists)
 354 were only found in the pineapple-banana treatments (PBIO and POF), and connectors
 355 (generalists) and module hubs (generalists) were found at the same time only in the
 356 pineapple-banana with the biofertilizer applied treatment (PBIO). Annotation
 357 information from all generalists showed that bacterial OTU2 and OTU3013 belonging
 358 to *Burkholderia* were generalists in the PBIO network but were absent in the POF and
 359 BOF networks. Additionally, another generalist OTU4869, from the PBIO network
 360 was identified as *Gp6* in Acidobacteria.

361
 362 **Figure 6. Z_i - P_i plot showing the distribution of OTUs based on their topological roles.**
 363 Each symbol represents an OTU in different treatment. BOF = banana continuously cropped
 364 with OF application; POF = banana-pineapple rotation with OF application in the banana
 365 season; PBIO = banana-pineapple rotation with BIO application in the banana season; The
 366 threshold values of Z_i and P_i for categorizing OTUs were 2.5 and 0.62, respectively, as
 367 proposed by Guimera and Amaral (2005) and simplified by Olesen et al. (2007).

368 **3.6 Relationship between microbial indicators and incidence of banana Fusarium**
 369 **wilt disease**

370 Bacterial and fungal structure (unweighted PCoA1), richness (Chao1), and Faith's PD;
 371 Ascomycota, Gemmatimonadetes, and Nitrospirae phyla relative abundances; and
 372 *Fusarium*, *Burkholderia*, and *Bacillus* genus relative abundances were selected in the
 373 linear model and explored for the best contribution factor of disease incidence (**Table**
 374 **3**).

375 **Table 3** Linear models (LM) for the relationships of microbial indicators with disease
 376 incidence and the relative importance of each indicator. *p* was the result from ANOVAs. The
 377 bold values represent *p* values lower than 0.05 from the ANOVA results.

	df	<i>F</i>	<i>p</i>	Relative Importance
Bac-PCoA1	1	304.09	<0.0001	19.32%
Fun-PCoA1	1	1.11	0.31	16.32%
Bac-Chao1	1	4.10	0.062	9.60%
Fun-Chao1	1	1.11	0.309	4.19%
Bac-Faith's PD	1	1.59	0.227	6.80%
Fun-Faith's PD	1	1.64	0.221	6.05%
Ascomycota	1	2.11	0.168	1.93%
<i>Fusarium</i> Relative abundance	1	1.01	0.332	8.23%
Nitrospirae	1	0.88	0.363	7.29%
Gemmatimonadetes	1	0.04	0.852	2.61%
<i>Burkholderia</i>	1	0.76	0.399	10.17%
<i>Bacillus</i>	1	0.33	0.574	3.29%
Residuals	14			

Model summary: $R^2 = 0.9417$, AIC =123.26, $p < 0.0001$
 Proportion of variance explained by model: 95.79%

378

379 Importantly, bacterial structure ($F = 304.09$, $p < 0.0001$, relative importance =
 380 19.32%), fungal structure ($F = 1.11$, $p < 0.31$, relative importance = 16.32%), and
 381 *Burkholderia* relative abundance ($F = 0.76$, $p < 0.399$, relative importance = 10.17%)
 382 contributed most in constraining disease incidence (with a relative importance greater
 383 than 10%).

384 In addition, based on linear regression analyses between disease incidence and
385 selected microbial indicators, we found that bacterial structure ($F = 304.09$, $p <$
386 0.0001 , relative importance = 19.32%) had a significant relationship with disease
387 incidence.

388 **4 Discussion**

389 In our previous research, the effectiveness of pineapple-banana rotation and
390 biofertilizer application was proven in the control of banana Fusarium wilt disease
391 (Wang et al., 2015; Fu et al., 2017). Soil microbial community change is an important
392 indicator of exploring the mechanisms behind these two control measures. In this
393 study, disease incidence and soil microbial community characteristics during the
394 banana-growing season were measured to evaluate the control effect and potential
395 impact of combined use of rotation and biofertilizer application.

396 Our previous results indicated that the pineapple-banana rotation treatments
397 significantly reduced the Fusarium wilt disease incidence when compared with
398 banana monoculture. Moreover, the application of biofertilizer enhances this
399 suppression ability. Similar to our results, Shen et al. (2018) reported that bio-
400 fertilizer application after fumigation with lime and ammonium bicarbonate revealed
401 higher effectiveness in controlling banana Fusarium wilt disease compared to bio-
402 fertilizer application or fumigation only. Although many control measures can slow
403 down the spread of Fusarium wilt disease, more effective control can be achieved by
404 the combined use of more than one measure (Pda et al., 2017). It was consistent with
405 this paper.

406 In this study, Chao1 and Faith's PD were significantly higher in the combined
407 rotation and biofertilizer treatment (PBIO) compared to the other two treatments
408 (BOF and POF). Previous studies have shown a positive correlation between disease

409 suppression and bacterial but not fungal diversity (Bonanomi et al., 2010; Fu et al.,
410 2017). Inconsistent with these results, pineapple-banana rotation and biofertilizer
411 treatment (PBIO) harbored a significantly higher fungal richness and diversity than
412 the other two treatments (BOF and POF). This agrees with some other previous
413 studies that observed the importance of fungal diversity in the suppressive capacity of
414 vanilla soils and potato cropping systems (Lu et al., 2013; Xiong et al., 2017). We
415 also observed that soil pH was increased in the rotation and biofertilizer treatment
416 (**Table S2**). Many previous studies have shown that microbial diversity has been seen
417 to increase with higher soil pH values (Liu et al., 2014; Shen et al., 2013). Therefore,
418 the high bacterial and fungal diversity observed in PBIO treatment may be attributed
419 to the high soil pH.

420 Both PCoA ordinations and MRT results revealed significant differences in
421 microbial community structure after rotation and biofertilizer applications. This is
422 supported by previous studies stating that rotation (Helena et al., 2016; Hartmann et
423 al., 2015) and biofertilizer application (Sun et al., 2015) altered the soil microbial
424 community composition. MRT analysis also revealed fertilization effects on microbial
425 community composition. These results are similar to previous results where
426 biofertilizer application was the dominant factor in determining microbial community
427 composition rather than temporal variability (Fu et al., 2017), suggesting a powerful
428 illustration of the necessity of biofertilizer application in pineapple-banana rotation
429 system.

430 Phylum-level results show that rotation and biofertilizer application decreased
431 the relative abundance of Ascomycota, and increased the relative abundance of
432 Chlamydiae, Gemmatimonetes, Nitrospire, Planctomycetes, and Verrucomicrobia,
433 which were all reported to be associated with disease suppression in previous reports
434 (Trivedi et al., 2017; Shen et al., 2018).

435 It is worth noting that our BIO was secondary fermentation with *Bacillus* added,
436 while the *Bacillus* genus was not enriched in the BIO treatment soil. Moreover, the
437 microbial structure appeared to be the most constrained factor in disease incidence in
438 linear models between microbial indicators and the incidence of banana Fusarium wilt
439 disease. Xiong et al (2017) suggested that microbial species introduced by
440 biofertilizer application induced wilt suppression by microbiome manipulation rather
441 than pathogen suppression directly. Thus, alteration of the soil microbiome may cause
442 a greater response than the added *Bacillus* in the PBIO treatment in our case.

443 Compared with bacteria, a higher percentage of *Fusarium*-related fungi genera
444 were observed in all treatments. Even though more kinds of bacteria are related to
445 *Fusarium*, a higher percentage of fungi showed relevance compared to bacteria. These
446 results agree with the findings of Mona et al. (2014) and Cai et al. (2017), who
447 reported that fungal communities have a more crucial response to soil factor changes
448 than bacterial communities. It is worth noting that fungal communities were more
449 dissimilar between the pineapple-banana rotation and maize-banana rotation
450 treatments than bacteria in our previous study (Wang et al., 2015). Thus, the higher
451 *Fusarium*-relevance observed in the fungal community in both the pineapple and
452 banana seasons further reinforced the importance of fungal community changes in our
453 case.

454 Several researchers have used microbial molecular ecological networks to study
455 complex microbial ecological systems in suppressed soils, including corn-potato
456 rotations (Lu et al., 2013) and vanilla (Xiong et al., 2017). In our study, the microbial
457 molecular ecological networks revealed distinct differences between the microbial
458 communities associated with the three treatments. More fungal OTUs were selected in
459 the PBIO treatment samples, followed by the POF and BOF treatments, based on the
460 F/B ratio. Although the OTUs selected to build the network were only a part of the

461 entire system, there is no doubt that these OTUs were very important for soil function
462 (Coyte et al., 2015). Therefore, we conclude that a large number of fungal OTUs
463 present in the system may have led to changes in soil function. PBIO, POF, and BOF
464 soils harbored modules with modularity values of 0.718, 0.642, and 0.616,
465 respectively, in this study. Modularity represents how well the network was organized
466 (Zhou et al., 2011). Thus, the PBIO network, which possessed high modularity, had
467 more connections between nodes in the same modules, followed by the POF and BOF
468 networks. The altered networks compared to POF and BOF networks may have
469 partially contributed latent attributes to higher disease suppression in PBIO treatment.
470 Furthermore, no module hubs (generalists) were present in the BOF network, whereas
471 all three module hubs were found in the pineapple-banana rotation network, as
472 indicated by the *Zi-Pi* relationship. In all three networks, connectors (generalists) and
473 module hubs (generalists) were found at the same time only in the PBIO treatment.
474 Generalists typically only occupy a small fraction of a community; however, the
475 presence of those generalists is very important (Zhou et al., 2011; Jens et al., 2011).
476 These nodes could have enhanced connectors within or among modules. If the
477 network is poorly connected or not connected at all, the community is predicted to be
478 disordered, and fluxes of energy, material, and information would not be efficient (Lu
479 et al., 2013). Therefore, in our case, these generalists found in the PBIO treatment
480 suggest that the microbial community structure of PBIO treatment was more orderly
481 and powerful than the other two treatments.

482 Annotation information from all generalists found in our study shows that
483 bacterial OTU2 and OTU3013 belong to *Burkholderia*, which were generalists in the
484 PBIO but not in POF and BOF networks. The linear model analysis also shows that
485 *Burkholderia* relative abundance constrained disease incidence with a higher relative
486 importance factor of 10.17%. Correspondingly, a high abundance of *Burkholderia* and

487 a high percentage of antagonistic *Burkholderia* were found during the pineapple
488 season in our previous report (Wang et al., 2015). *Burkholderia* is a versatile
489 organism due to its powerful ability to occupy ecological niches and a variety of
490 functions, including biological control and plant growth promotion in agriculture
491 (Coenye and Vandamme, 2003). Thus, even though the relative abundance of
492 *Burkholderia* in the PBIO treatment was not that high, its change in network structure
493 may have been attributed to the general wilt suppression activity, which is the special
494 function of *Burkholderia*. Additionally, one generalist in the PBIO treatment sample
495 was identified as *Gp6* in Acidobacteria. Although no Acidobacteria antimicrobial
496 activities have previously been recorded, several studies have demonstrated that
497 Acidobacteria is greatly affected by soil pH and that the *Gp6* is positively correlated
498 with soil pH (Bartram et al., 2014; Jones et al., 2009).

499 **5 Conclusions**

500 This study was an expansion of our previous work. The results revealed that
501 pineapple-banana rotation combined with biofertilizer application during the banana
502 season effectively reduced the *Fusarium* spp. abundance and banana Fusarium wilt.
503 Both bacterial and fungal taxonomic and phylogenetic α -diversity was increased by
504 rotation and biofertilizer application. Between the two strategies, biofertilizer
505 application affected both bacterial and fungal community composition more
506 predominantly compared to rotation. A higher percentage of *Fusarium*-related fungal
507 phyla was observed compared to bacterial. More specifically, the potentially
508 beneficial *Burkholderia* genus may attribute to the general wilt suppression activity
509 for its important role in network structure and its high relative importance in linear
510 models. Pineapple-banana rotation combined with biofertilizer application has strong
511 potential for the sustainable management of banana Fusarium wilt disease.

512 **Data availability**

513 All data are available. The sequencing data have been submitted to the NCBI
514 Sequence Read Archive database (SRP234066).

515 **Author contributions**

516 Rong Li and Beibei Wang designed the research and wrote the manuscript. Beibei
517 Wang, Yannan Ou and Zongzhuan Shen performed trials and conducted field work.
518 Beibei Wang and Jinming Yang analyzed the data. Rong Li, Mingze Sun, Lin Fu,
519 Yunze Ruan, Yan Zhao and Qirong Shen participated in the design of the study,
520 provided comments and edited the manuscript. All authors read and approved the
521 final manuscript.

522 **Competing interests**

523 The authors declare that the research was conducted in the absence of any commercial
524 or financial relationships that could be construed as a potential conflict of interest.
